Moment = Force x Distance; Shear = rate of change of moment (a.k.a derivative or slope of moment) If shear is zero, bending moment is constant (can also be zero). BMD is continuous. AFDs and SFDs may not be continuous. Fixed ends have moment reactions. Pinned/roller ends do NOT have moment reactions, but they can have externally applied moment.

This interaction is used to estimate the maximum shear and moment that is likely to be developed in the beam during extreme earthquake shaking. These shear and moment estimates can be used to design the connections for the beam-column interface. Beam length-to-depth ratios for which the shear-moment interaction becomes significant are calculated.

A simple interaction equation for the strength of the stringer- and ringer-stiffened cylinders under a combined axial compression and external pressure can be expressed as (18.40) $(\sigma/\sigma_m) + (p/p_{hc})^n \leq 1$ where σ and p are the applied axial compressive stress and radial pressure, respectively. Ellinas et al. (1984) recommended that $m = n = 2$.

The plot of axial capacity (Pn) vs. moment capacity (Mn) is called an interaction diagram. Each point on the interaction diagram is associated with a unique strain profile for the column cross-section. An interaction diagram has three key points, as shown in the figure below. Each point and each region between the points is discussed below.

Moment-shear-axial force interaction in composite beams ...

Shear wall-frame interaction for lateral load resistance is complex because shear walls deflect primarily in bending mode, while frames deflect in shear mode. However, the interaction between shear walls and frames is beneficial for high-rise buildings, since the linkage and stiffness of the floor slab diaphragm and the stabilising elements give better lateral load resistance.

Shear Wall-Frame Interaction in High-Rise Buildings ...

Bending, shear and axial force. Where $V_{Ed} \leq 0.5V_{pl,Rd}$, no reduction of the resistances defined for bending and axial force need be made. Where $V_{Ed} > 0.5V_{pl,Rd}$, the design resistance of the cross-section to combinations of moment and axial force should be calculated using a reduced yield strength, as given for bending and shear.

Axial Forces: Up to five compressive axial forces may be specified to generate moment-curvature relationships for each cross-section. One of the following three formats may be selected to input the axial forces for each section: (1) percentage of the balanced axial force; (2) percentage of the axial force capacity under concentric loading; and (3) numeric values of the axial forces.
