A hydrologic model is a simplification of a real-world system (e.g., surface water, soil water, wetland, groundwater, estuary) that aids in understanding, predicting, and managing water resources. Both the flow and quality of water are commonly studied using hydrologic models.

Modelling approach and the model to be used are problem specific, no single model or approach can be used to solve all problems, and there are constraints in each situation.

Modellers therefore need to have a choice when confronted with constraints such as lack of sufficient data, resources, expertise and time.

managers face today. This book practically demonstrates the key processes, methods, and models used in studying environmental management.

Arid and semi-arid regions are defined as areas where water is at its most scarce. The hydrological regime in these areas is extreme and highly variable, and they face great pressures to deliver and manage freshwater resources. However, there is no guidance on the decision support tools that are needed to underpin flood and water resource management in arid areas. UNESCO initiated the Global network for Water and
